

A simple random sample of 50 items from a population with population standard deviation is 6 resulted in a sample mean of 32. Provide a 95% confidence interval for the population mean.

Perform Chi Square test on the given data:

Qualification/Marital Status	Middle School	High School	Bachelors	Masters	PhD	Total
Unmarried	18	36	21	9	6	90
Married	12	36	45	36	21	150
Divorced	6	9	9	3	3	30
Widowed	3	9	9	6	3	30
Total	39	90	84	54	33	300

Ho: There is no link between married status and degree.

H1: there is link between them.

$$\chi^2 = \sum \frac{(O - E)^2}{E}$$

Now, for the expected value(E) we get,

$$\text{expected count} = \frac{\text{row total} \cdot \text{column total}}{\text{table total}}$$

Qualification	Middle school (E <sub>1</sub> )	High School (E <sub>2</sub> )	Bachelors (E <sub>3</sub> )	Masters (E <sub>4</sub> )	PhD (E <sub>5</sub> )	Total
Unmarried	11.7	27	25.2	16.2	9.9	90
Married	19.5	45	42	27	16.5	150
Divorced	3.9	9	8.4	5.4	3.3	30
Widowed	3.9	9	8.4	5.4	3.3	30
Total	39	90	84	54	33	300

Now we have to calculate the term (O-E)<sup>2</sup>

Hence we get,

Unmarried	39.69	81	17.64	51.84	15.21	
married	56.25	81	9	81	380.25	
Divorced	4.41	0	0.36	5.76	0.09	
Widowed	0.81	0	0.36	0.36	0.09	

∴ As per,  $\chi^2 = \sum \frac{(O - E)^2}{E}$ , we get following table:

Unmarried	9.99	3	0.7	3.2	1.53 →	11.82
Married	2.88	1.8	0.21	3	23.04 →	30.93
Divorced	1.13	0	0.04	1.06	0.02 →	2.25
Widowed	0.20	0	0.04	0.06	0.02 →	0.32
						45.32

∴ We get,  $\chi^2_{\text{stat}} = 45.32$

---

Now,

Degree of Freedom = (Row-1)\*(Column-1)

$$= (4-1)*(5-1)$$

$$= 12$$

∴ We get,  $\chi^2_{\text{critical}} = 21.02$  .....( after referring Chi Square Table, with DF= 12 and  $\alpha = 0.95$  )

∴  $\chi^2_{\text{stat}} > \chi^2_{\text{critical}}$

∴ There is a link between them.
